

Befund - How the audit works

Purchase-to-Pay compliance on price changes · Neo4j Aura + agentic GraphRAG · 319/319 against reference answers

1 · What happens when someone types an order number

Everything above the dotted line is computed. Only the closing paragraph is written by a language model.

2 · The graph model for one purchase order item

The POItem is the hub: process, contract and evidence meet on one node, so the whole case is one traversal.

3 · What it produces, and how it is checked

Every run is scored against 1.135 reference answers written before the system existed.

319 of 319 agree with the reference answers - a clean diagonal, no confusion between classes.

The remaining 162 are not assessable: no framework contract covers that supplier, so there is no notice period to test against. Saying so is itself a finding.

Why a graph and not a vector index: asked how many days' notice was given, search over the whole corpus returns the WRONG supplier's price letter with a higher similarity score (0.754) than the right one (0.744). Narrowing to the item's own documents first makes it correct. Vector search finds similar text; the graph finds related text - an audit needs related.

Synthetic document corpus. Tolerance and approval-authority checks are reported but not validated against reference answers.
